

How Malone Global University Uses Artificial Intelligence

Overview

Malone Global University uses artificial intelligence as a research, drafting, organizational, and technical tool. It is not intended to replace human judgment, lived experience, or institutional responsibility.

The basic distinction is straightforward: **reference material should emphasize verification, documentation, and neutrality, while opinion, criticism, strategy, and interpretation require a stronger human voice.**

Artificial intelligence is therefore used differently depending on the purpose of the document.

Why I Use Artificial Intelligence

I use artificial intelligence extensively for a practical reason: **it saves time.**

At present, I do not have paid staff or volunteers assisting with the large amount of research, writing, editing, coding, classification, and website development required to build Malone Global University and its related institutions.

Artificial intelligence allows one person to perform work that would otherwise require a much larger research, editorial, and technical staff. It can help organize information, compare sources, identify relevant scholarship, generate initial drafts, standardize reference pages, troubleshoot code, and accelerate routine production.

This does not mean that artificial intelligence determines what Malone Global University believes.

For neutral or reference-oriented documents, I may rely heavily on AI-assisted drafting and then review the resulting material. For documents based on my lived experience, political analysis, strategic judgment, institutional philosophy, or speculation about the strategies of other actors, I either write the material myself or substantially revise AI-generated drafts.

The distinction matters because **research assistance and human judgment are not the same function.**

Artificial Intelligence and Information Access

I have also heard the argument that part of the growing backlash against artificial intelligence reflects concern that ordinary individuals can now use tools once available primarily to large institutions, professional research staffs, corporations, governments, universities, and media organizations.

Whether that interpretation ultimately proves correct is a matter of debate.

What is clear is that artificial intelligence can substantially reduce the resources required to research complicated subjects and construct serious arguments. A person working independently can now locate competing interpretations, examine historical material, identify relevant academic research, compare claims, and develop research-grounded alternatives to established narratives much more rapidly than before.

That capability has significant implications for who can participate in intellectual and political debate.

The Social Media Problem

One of the central problems with social media is not simply that false information exists. The deeper problem is often **lack of accountability, transparency, classification, and context**.

A social-media account may provide little information about who operates it, the operator's background, financial interests, political motives, institutional affiliations, methodology, or standards of evidence.

The reader may also have difficulty determining whether a particular statement is:

- verified fact;
- interpretation;
- personal testimony;
- speculation;
- allegation;
- satire;
- propaganda; or
- some mixture of these categories.

Short-form platforms make the problem worse because complicated subjects are compressed into posts, clips, captions, and slogans with little room for qualification or context.

This structure makes social media particularly vulnerable to misinformation and oversimplification. Even technically accurate statements can become misleading when essential context is removed.

MGU should therefore attempt to make the status of information clearer rather than merely asking readers to trust the institution publishing it.

Reference Material and Source Transparency

Artificial intelligence can be useful in this environment because it can assist with locating, comparing, summarizing, and organizing information from multiple sources.

That does not mean AI-generated information is automatically reliable, nor does artificial intelligence itself constitute peer review.

When properly used, however, AI can help identify government records, academic scholarship, primary documents, reputable journalism, legal materials, and peer-reviewed research that can then be examined and cited.

The authority of an MGU reference page should therefore come from **the quality of its evidence and sources**, not from the fact that artificial intelligence helped produce it.

For this reason, reference materials in the MGU Library should generally use an impersonal, evidence-oriented style. AI-assisted drafting is particularly useful here because the purpose of these pages is to explain what the available evidence establishes rather than express the author's emotional reaction to that evidence.

Reference Material Versus Opinion

MGU should maintain a clear editorial distinction between its reference library and its interpretive publications.

MGU Library and Encyclopedia materials should emphasize:

- factual accuracy;
- documentation;
- citations;
- competing interpretations where materially relevant;
- neutral language;
- clear distinctions between established fact and unresolved questions.

AI assistance can play a substantial role in producing these materials.

Panther Opinions, Panther Perspectives, media criticism, institutional commentary, and strategic analysis serve a different purpose.

These publications may involve:

- lived experience;
- moral judgment;
- criticism;
- political analysis;
- institutional priorities;
- speculation;
- interpretation of current events;
- strategic recommendations.

These subjects require human authorship or substantial human editorial control because their purpose is not merely to catalogue information. They seek to interpret what that information means.

The Limits of Artificial Intelligence

Artificial intelligence makes mistakes.

Sometimes those mistakes take the form commonly called hallucinations: invented facts, incorrect citations, confused dates, or unsupported claims.

Other mistakes are more subtle.

An AI system may possess considerable general information while lacking access to a particular document, local experience, private conversation, community history, institutional record, or piece of context necessary to interpret an event correctly.

The resulting answer may be technically sophisticated while still missing something fundamental.

Artificial intelligence can therefore produce both impressive insights and serious errors in judgment.

Its output must be evaluated rather than treated as authoritative merely because it sounds professional.

The Distance of Academic Language

A similar limitation can exist in academic literature.

Scholarly research is indispensable, but academic writing frequently observes communities from a distance. Researchers may describe human experience through the specialized languages of sociology, psychology, philosophy, economics, political science, or law.

Those disciplines can provide valuable analytical tools, but technical language can also obscure what an experience actually feels like to the people living through it.

There is a difference between describing an event statistically and describing how that event operates in someone's everyday life.

There is also a difference between observing a community and belonging to that community.

For this reason, lived experience should not automatically be dismissed merely because it is expressed in ordinary language rather than academic terminology.

The challenge is to combine both forms of knowledge.

Scholarship can establish patterns, historical context, comparison, and evidence. Human testimony can explain proximity, consequences, perception, emotion, and meaning.

Neither should automatically cancel the other.

Race and the Limits of Mechanical Analysis

Racial issues illustrate this problem particularly well.

Artificial intelligence can be highly useful when examining the documented history of slavery, segregation, discrimination, civil-rights law, political movements, demographic patterns, court decisions, government policy, and academic research.

It becomes less authoritative when asked to determine how contemporary racial experiences should be interpreted morally, socially, or strategically.

Race is not simply a database variable. It is also a historical, political, cultural, institutional, and lived phenomenon.

An artificial intelligence system does not personally experience discrimination, fear, humiliation, solidarity, community memory, or the social consequences associated with racial classification.

That does not make AI useless when discussing racism. It means its role must be understood correctly.

AI can help establish the evidentiary record.

Human beings must still interpret what that record means.

Emotion, Reason, and Truth

Objectivity should not be confused with emotional emptiness.

A cold description of an event is not automatically more truthful merely because it sounds detached. At the same time, emotional intensity does not make a claim morally or factually correct.

Both errors should be avoided.

Human societies do not operate solely through mechanical assessments of facts. People also make judgments about justice, responsibility, dignity, loyalty, obligation, harm, courage, and morality.

These values cannot be reduced entirely to statistics.

The objective should therefore not be to remove human emotion from intellectual work. It should be to prevent emotion from replacing evidence while also preventing detached analysis from erasing the human meaning of the evidence.

The MGU Standard

MGU's approach should combine the strengths of human and artificial intelligence while recognizing the limitations of both.

Artificial intelligence should assist with research, organization, comparison, drafting, coding, verification, and reference production.

Human authorship should remain central where lived experience, moral judgment, institutional philosophy, criticism, political interpretation, or strategic reasoning is involved.

Sources should be visible.

Fact should be distinguished from interpretation.

Interpretation should be distinguished from speculation.

Artificial intelligence should be checked.

Human assumptions should also be checked.

The ultimate objective is neither artificial intelligence nor human intuition by itself.

The objective is **better reasoning, better documentation, greater transparency, and a more accurate understanding of the world being examined.**
